WORLD CONGRESS OF EPIDEMIOLOGY 2024

Introduction

- Infectious Respiratory Diseases (IRDs) among leading causes of morbidity and mortality^{1,2}
 - Lower Respiratory Tract Infections (**LRTI**): **2.5M deaths**, 100M DALYs in 2019
 - **COVID-19: 14.9M excess deaths** in 2020/21
 - Upper Respiratory Tract Infections (**URTI**): 6.4M DALYs, **17.2B cases** in 2019
- Association between adiposity and severe IRD first studied more extensively during the COVID-19 pandemic
 - Previous studies have limitations:
 - Focus on **Body-mass index** as adiposity measure
 - **Confounding** due to lack of comprehensive data collection
 - Susceptible to **reverse causation bias**
 - Role of **comorbidities** unclear

Methods

- UK Biobank
 - 2006-2010: recruited 502,599 participants (40-69 years)
 - Exposure assessment: **anthropometrics** and **bioelectrical impedance**
 - Follow-up: linkage to **electronic hospital** or **death records**

Methods

- UK Biobank
 - 2006-2010: recruited 502,599 participants (40-69 years)
 - Exposure assessment: **anthropometrics** and **bioelectrical impedance**
 - Follow-up: linkage to **electronic hospital** or **death records**

- IRD endpoint definition
 - **severe**
 - **incident**
 - **community-acquired**

Methods

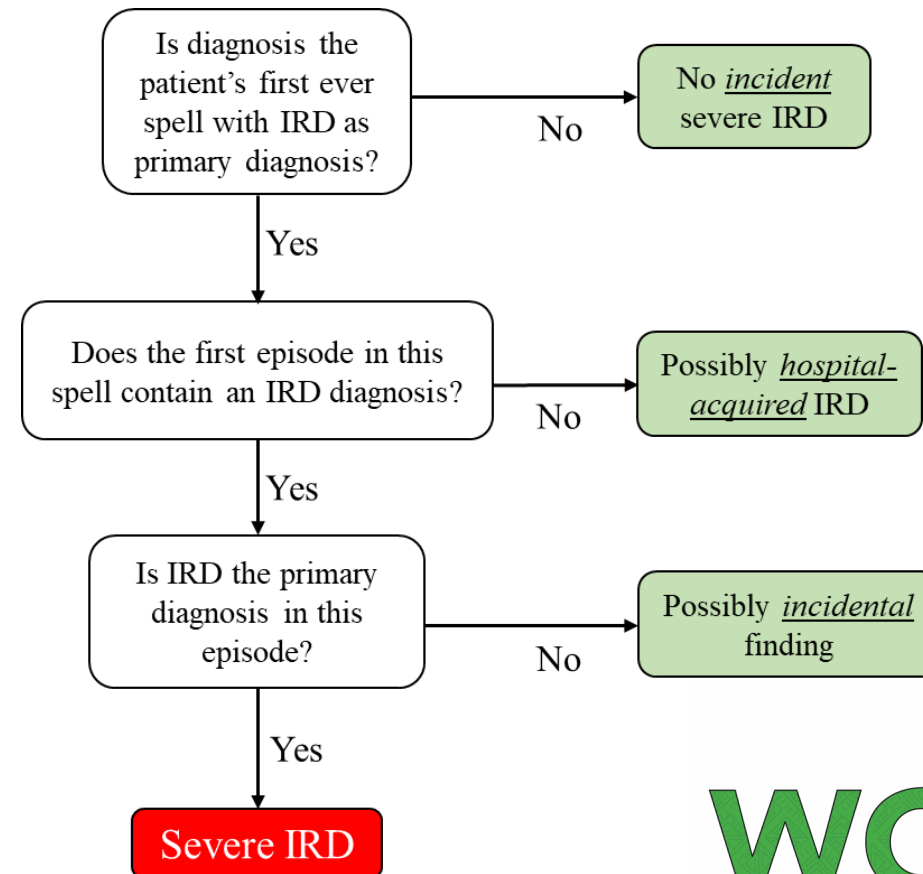

- UK Biobank
 - 2006-2010: recruited 502,599 participants (40-69 years)
 - Exposure assessment: **anthropometrics** and **bioelectrical impedance**
 - Follow-up: linkage to **electronic hospital** or **death records**

- IRD endpoint definition

- **severe**
- **incident**
- **community-acquired**

- 3 IRD subtypes

- **LRTIs:** J09-J22
- **COVID-19:** U07
- **URTIs:** J00-J06

Methods

- Exclusion criteria
 - Missing/extreme body composition (e.g. BMI < 15 or > 50 kg/m²)
 - Prevalent chronic respiratory diseases, previous hospitalization for IRD

Methods

- Exclusion criteria
 - Missing/extreme body composition (e.g. BMI < 15 or > 50 kg/m²)
 - Prevalent chronic respiratory diseases, previous hospitalization for IRD
- Statistical methods
 - Cox proportional hazards models (adjusted for socio-demographic and lifestyle factors)
 - By levels of adiposity
 - Per 1-SD higher *usual* adiposity (i.e. corrected for regression dilution)
 - Assessing effect modification by socio-demographic and lifestyle factors

Methods

- Exclusion criteria
 - Missing/extreme body composition (e.g. BMI < 15 or > 50 kg/m²)
 - Prevalent chronic respiratory diseases, previous hospitalization for IRD
- Statistical methods
 - Cox proportional hazards models (adjusted for socio-demographic and lifestyle factors)
 - By levels of adiposity
 - Per 1-SD higher *usual* adiposity (i.e. corrected for regression dilution)
 - Assessing effect modification by socio-demographic and lifestyle factors
 - Sensitivity analyses
 - Excluding early follow-up and ever smokers
 - Excluding prevalent (at baseline) or incident (acquired during follow-up) chronic disease

Results

- 456,393 participants after exclusions
 - Median age 58 years
 - 55% women
 - 12 years mean follow-up
 - 94% of 'White' ethnicity
 - Healthy volunteer effect
 - higher education and income
 - 55% never smokers

Results

- 456,393 participants after exclusions
 - Median age 58 years
 - 55% women
 - 12 years mean follow-up
 - 94% of 'White' ethnicity
 - Healthy volunteer effect
 - higher education and income
 - 55% never smokers
- 22,458 severe IRD events
 - 17,524 severe LRTIs
 - 3386 severe COVID-19
 - 1548 severe URTI

Results

- LRTI: J-shape
 - log-linear in upper 80%

Stratified by 5-year age-at-risk group, and adjusted for standing height (except BMI), ethnicity, smoking status, education, UK region, socioeconomic deprivation, and alcohol consumption

WCE

WORLD CONGRESS OF EPIDEMIOLOGY 2024

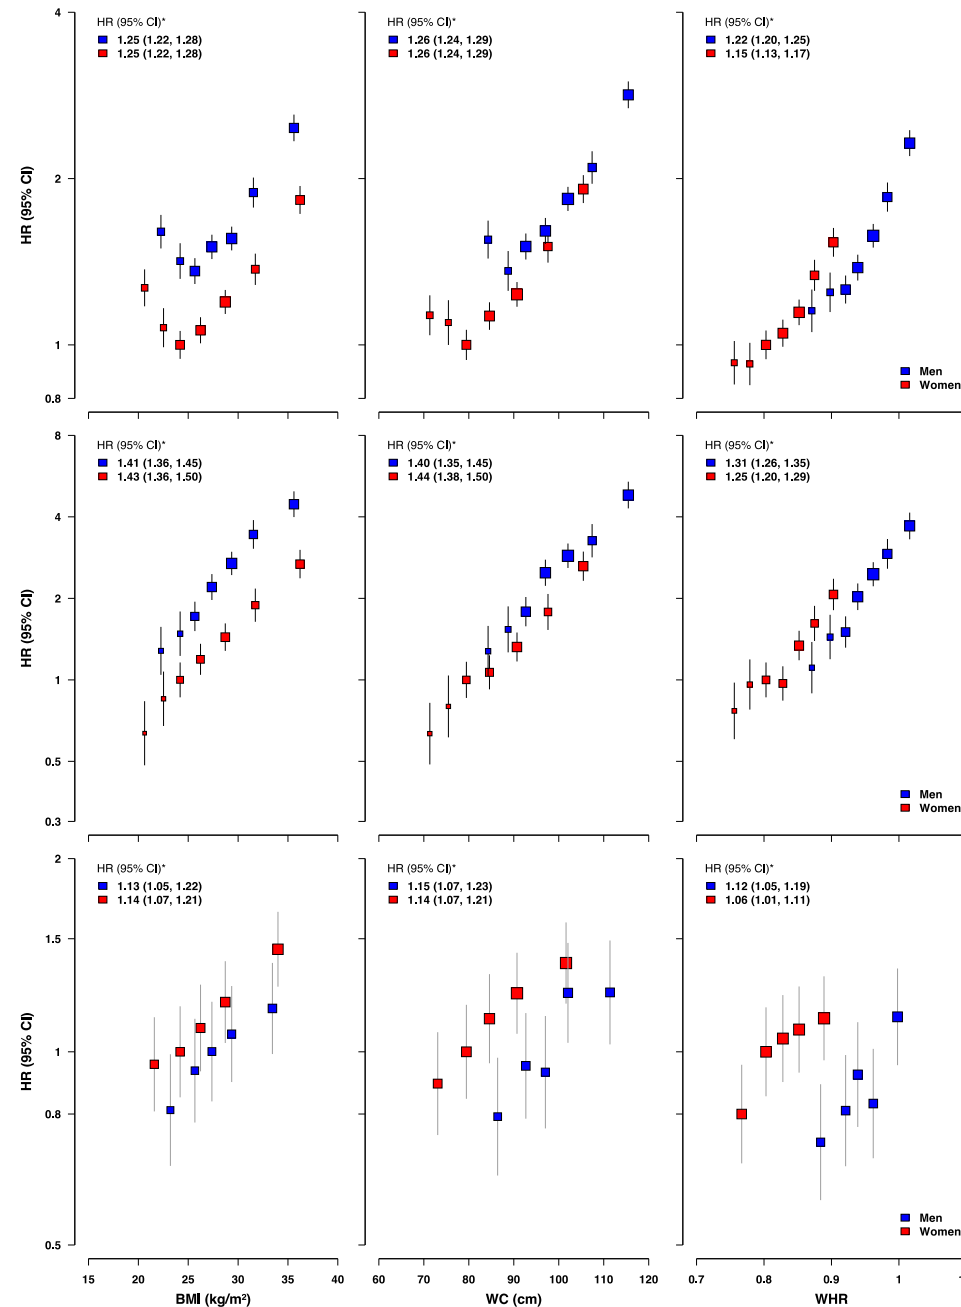

Results

- **LRTI:** J-shaped
 - log-linear in upper 80%

- **COVID-19:** log-linear

- **URTI:** log-linear

Stratified by 5-year age-at-risk group, and adjusted for standing height (except BMI), ethnicity, smoking status, education, UK region, socioeconomic deprivation, and alcohol consumption

Results

Body-mass index

Waist circumference

Waist-hip ratio

LRTI

COVID-19

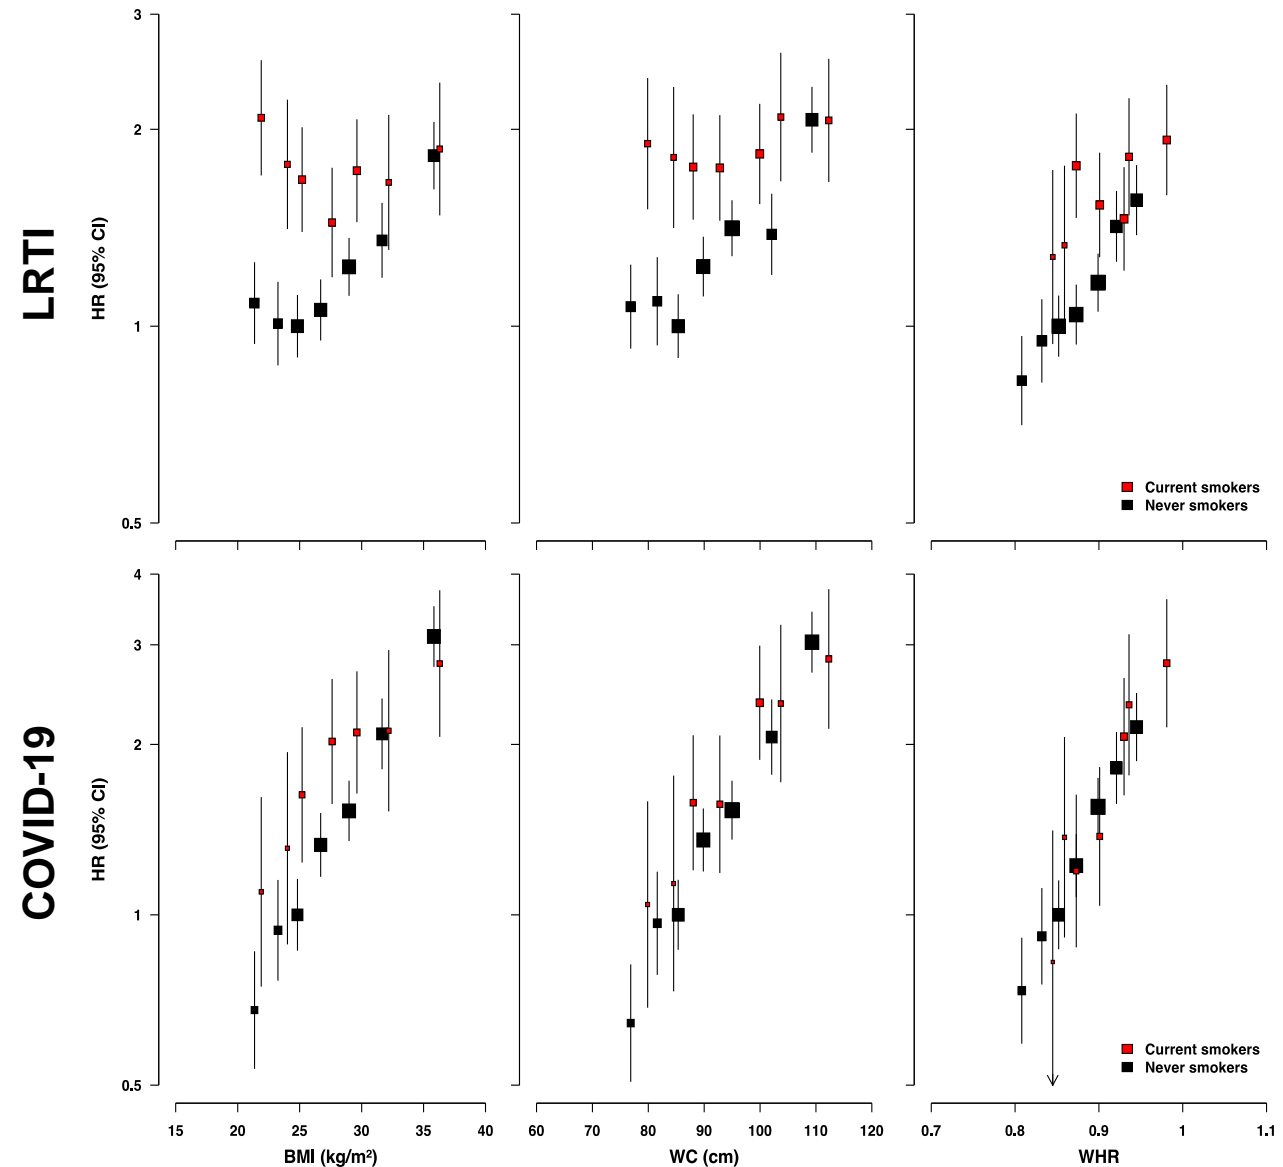

URTI

- LRTI: **~25%** excess risk per usual SD (in upper 80%)
- COVID-19: **~40%** excess risk
- URTI: **~10%** excess risk
- Effect modification by age, but not by sex, education, UK country, or deprivation

Results

- Stronger associations in never smokers (LRTI, COVID-19)
- **Reverse causation:**
 - **LRTI:** attenuation of J-shape when excluding 10 years of follow-up and ever smokers
 - **COVID-19:** log-linear due to 10-14 years between baseline assessment and pandemic

Key findings

- Strong, log-linear associations of adiposity with risk of hospitalisation or death from severe LRTI (in upper 80%), COVID-19, and URTI
- Similar association strengths between COVID-19 and other LRTIs (~40% and ~25% excess risk per usual SD, respectively) might suggest shared biological mechanisms
- Associations with severe LRTI likely affected by reverse causation, but mostly robust to observational sensitivity analyses
- Associations predominantly accounted for by central adiposity (WC and trunk fat), despite similar strength of association
- Limitations:
 - Limited testing for LRTI and URTI causative agent → no further subdivision possible for different types of LRTI and URTI
 - UK Biobank has low ethnic variation → limited generalisability to other ethnicities
