

# Miscarriage in relation to financial hardship in childhood, adolescence, and adulthood

Sharonda M. Lovett, MPH

Doctoral Candidate of Epidemiology

Boston University School of Public Health (USA)

[slovett1@bu.edu](mailto:slovett1@bu.edu)

# Background

- Financial hardship has been associated with subfertility, ovarian decline, and early menopause, yet its effect on miscarriage (pregnancy loss <20 weeks) is less clear
- Life course conceptual models + novel epidemiologic methods provide a framework to postulate direct effects of interest

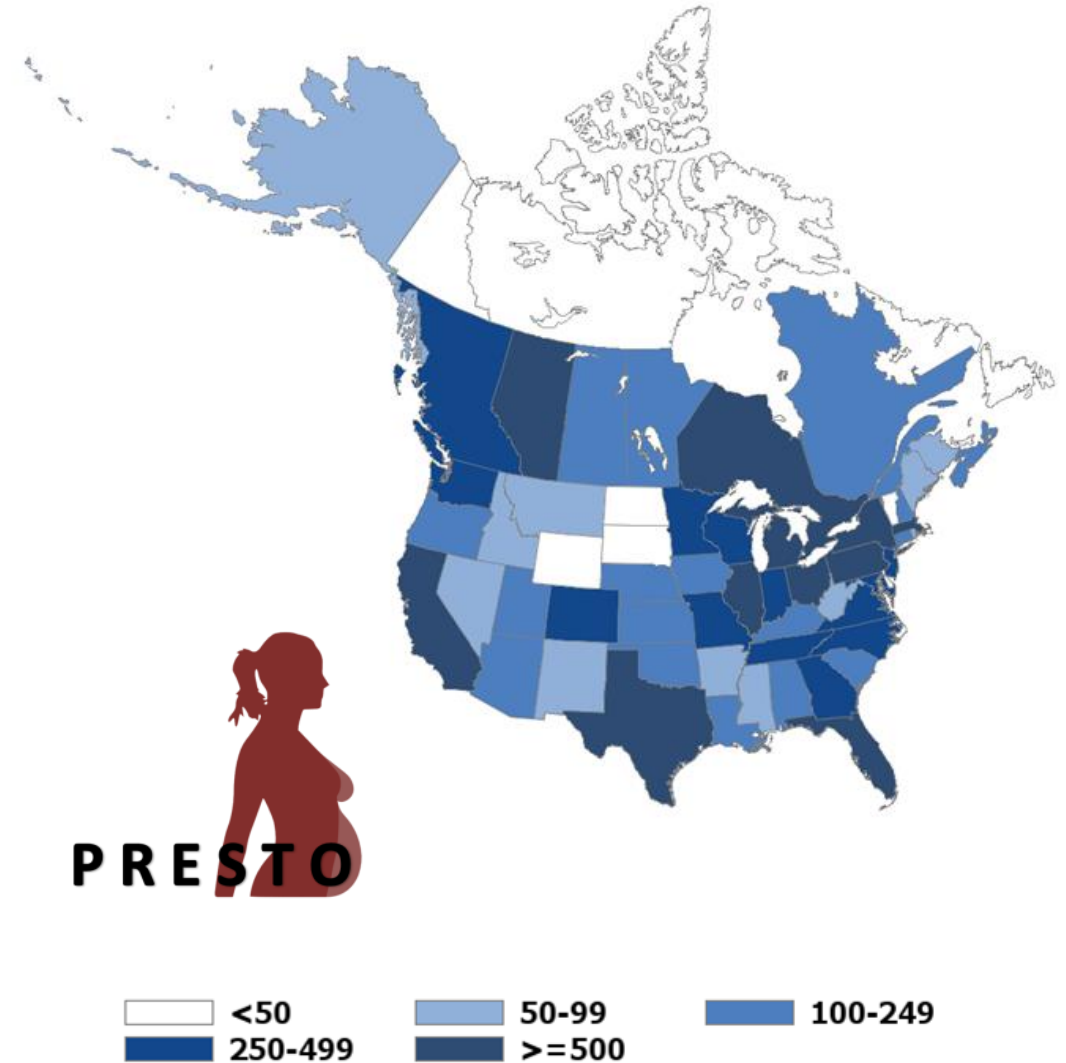

**Study Objective: To estimate the effect of financial hardship during  
1) specific life stages, and 2) cumulatively across the life course, on miscarriage**

# Study Population

To learn more about the study:

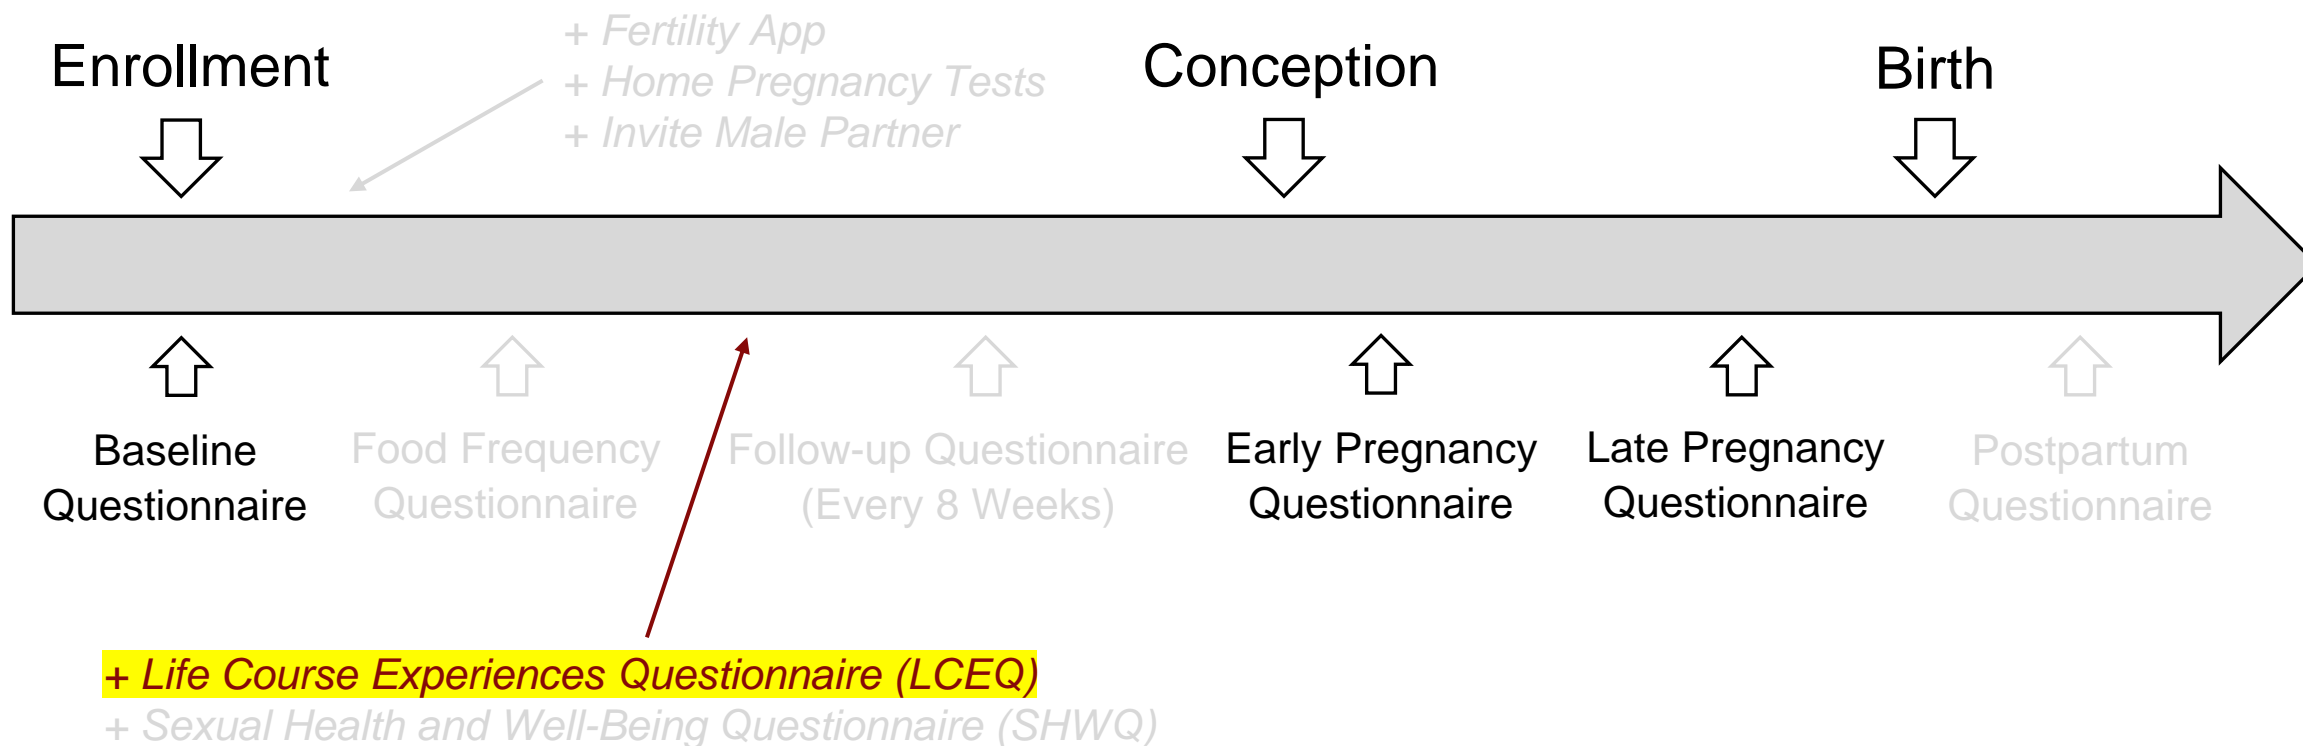

- Pregnancy Study Online (PRESTO):  
a prospective preconception cohort study
  - Assigned female sex at birth
  - Aged 21-45 years
  - Residents of the USA or Canada
  - Planning pregnancy
- Recruited using internet-based methods (e.g., online ads) and word of mouth

# Study Design

To learn more about the study:

# Assessment of Financial Hardship

- “In your household, has there ever been a time when you or your family...”
  - “Did not have enough money to pay for food, rent, or mortgage?”
  - “Had to borrow money to pay for medical expenses?”
  - “Received public assistance or welfare?”

**Childhood**  
(age  $\leq 11$ )

**Adolescence**  
(ages 12-17)

**Adulthood**  
(age  $\geq 18$ )

# Assessment of Miscarriage

- “Since your last questionnaire, have you had any of the following?”
  - Miscarriage (including chemical pregnancy)
  - Blighted ovum
  - Ectopic pregnancy (*Censored*)
  - Induced abortion (*Censored*)
- “How many weeks did the pregnancy last?”
- “What was the date of your first positive pregnancy test?”

# Statistical Analysis

- Cox proportional hazards regression to estimate hazard ratios (HRs) and 95% CIs
  - Time scale: Gestational weeks
  - Time zero: Gestational week at first positive pregnancy test
  - $HR > 1.0$  indicates increased miscarriage risk
- Used inverse probability of selection weights (IPSW) and treatment weights (IPTW)
  - To address potential selection bias from differential completion of the LCEQ
  - To adjust for time-dependent confounding

# Models

|       | Critical Periods  | Accumulation of Risk  |
|-------|---|---|
| What? | Identifies specific life stages when exposure may be harmful  | Suggests the effects of exposure accumulate over time, irrespective of life stage                               |
| How?  | Using separate regressions, model financial hardship during each life stage compared to no financial hardship during that life stage as the reference | Model financial hardship during adolescence and adulthood within strata of prior exposure to financial hardship |

*Critical Periods model, where only child financial hardship has a direct influence on miscarriage*

# Models

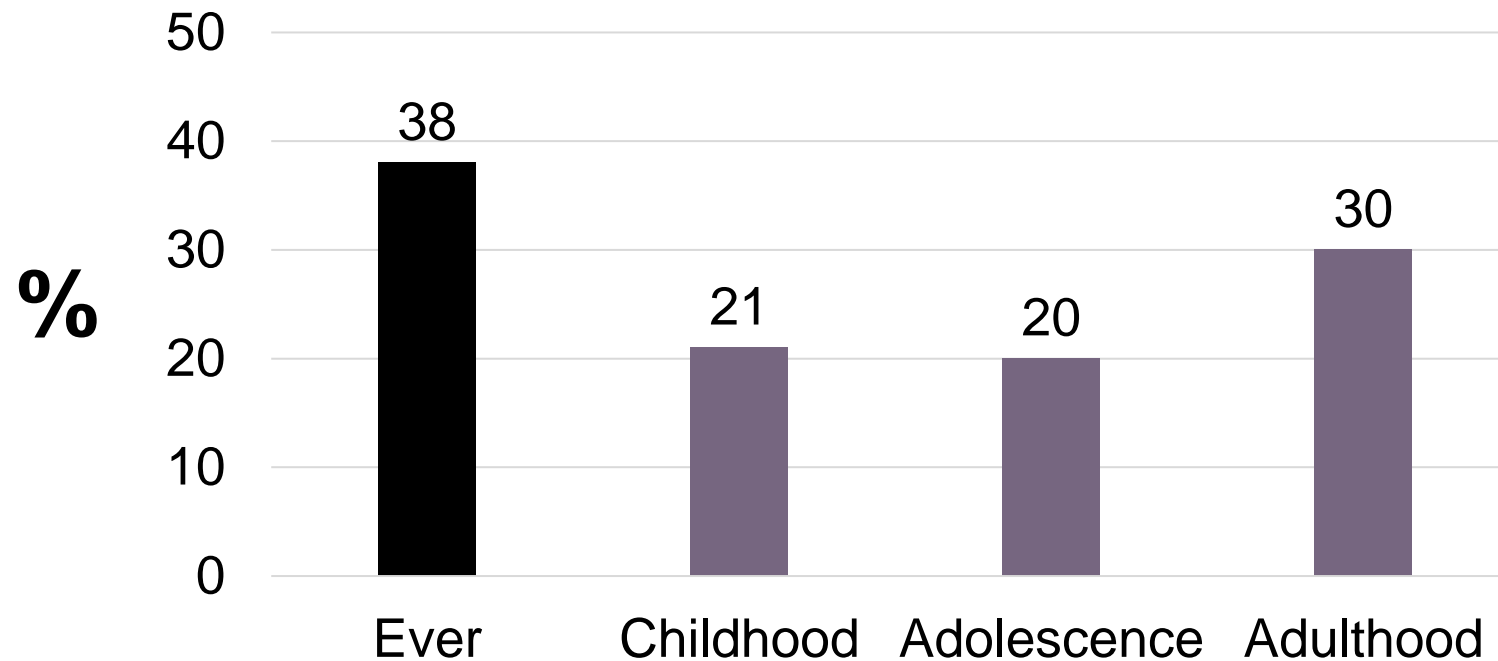

|       | Critical Periods  | Accumulation of Risk  |
|-------|---|---|
| What? | Identifies specific life stages when exposure may be harmful  | Suggests the effects of exposure accumulate over time, irrespective of life stage                               |
| How?  | Using separate regressions, model financial hardship during each life stage compared to no financial hardship during that life stage as the reference | Model financial hardship during adolescence and adulthood within strata of prior exposure to financial hardship |

*Accumulation of Risk model*

# Results

- Among 5,585 participants, 23% reported miscarriage
- Financial hardship was most often experienced during adulthood

# Results: Sample Demographics

Mean age = 31 years  
13% BIPOC

26% with depression diagnosis  
27% with anxiety diagnosis

85% with Bachelor's degree  
88% are currently employed

29% with child trauma  
42% with adolescent trauma

13% with  $\geq 7$  alcoholic drinks/week  
4% are current smokers

86% with private health insurance  
25% with history of miscarriage

# Results: Critical Periods

## Childhood critical period

No child FH

1.00 (Reference)

Child FH

1.17 (1.00, 1.38)

## Adolescence critical period

No adolescent FH

1.00 (Reference)

Adolescent FH

1.07 (0.89, 1.29)

## Adulthood critical period

No adult FH

1.00 (Reference)

Adult FH

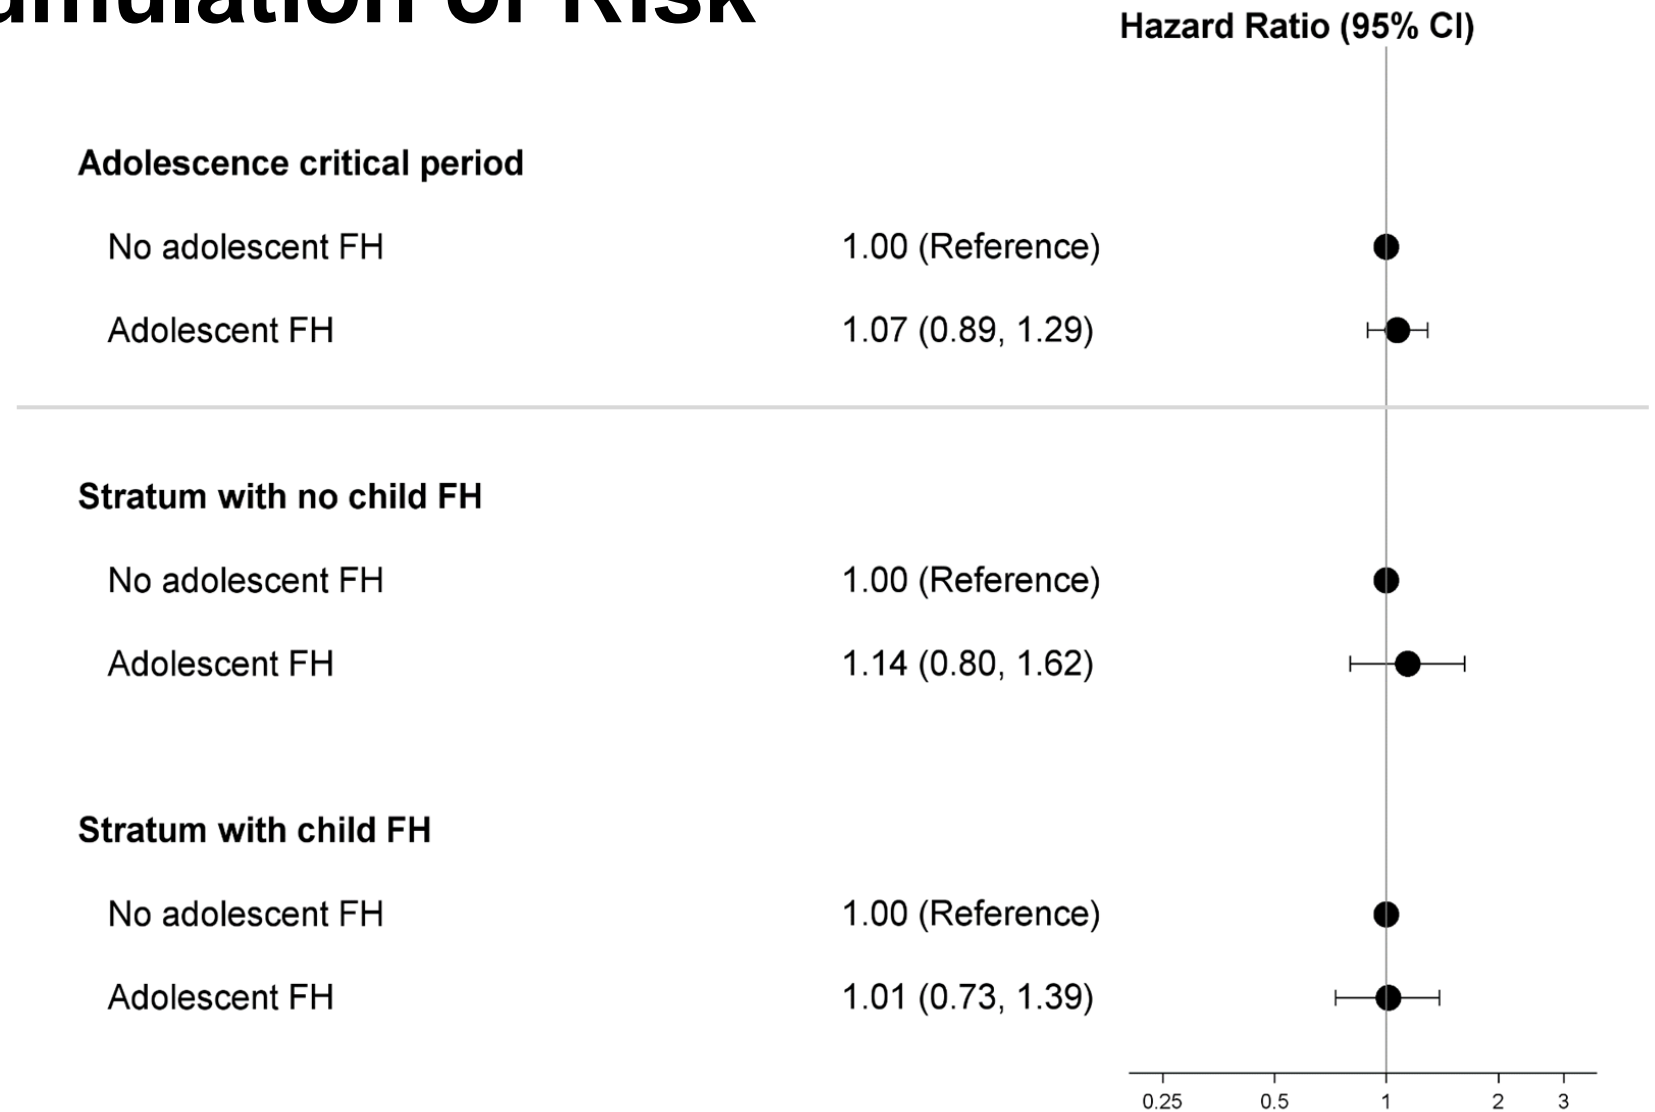

1.10 (0.95, 1.28)

Hazard Ratio (95% CI)

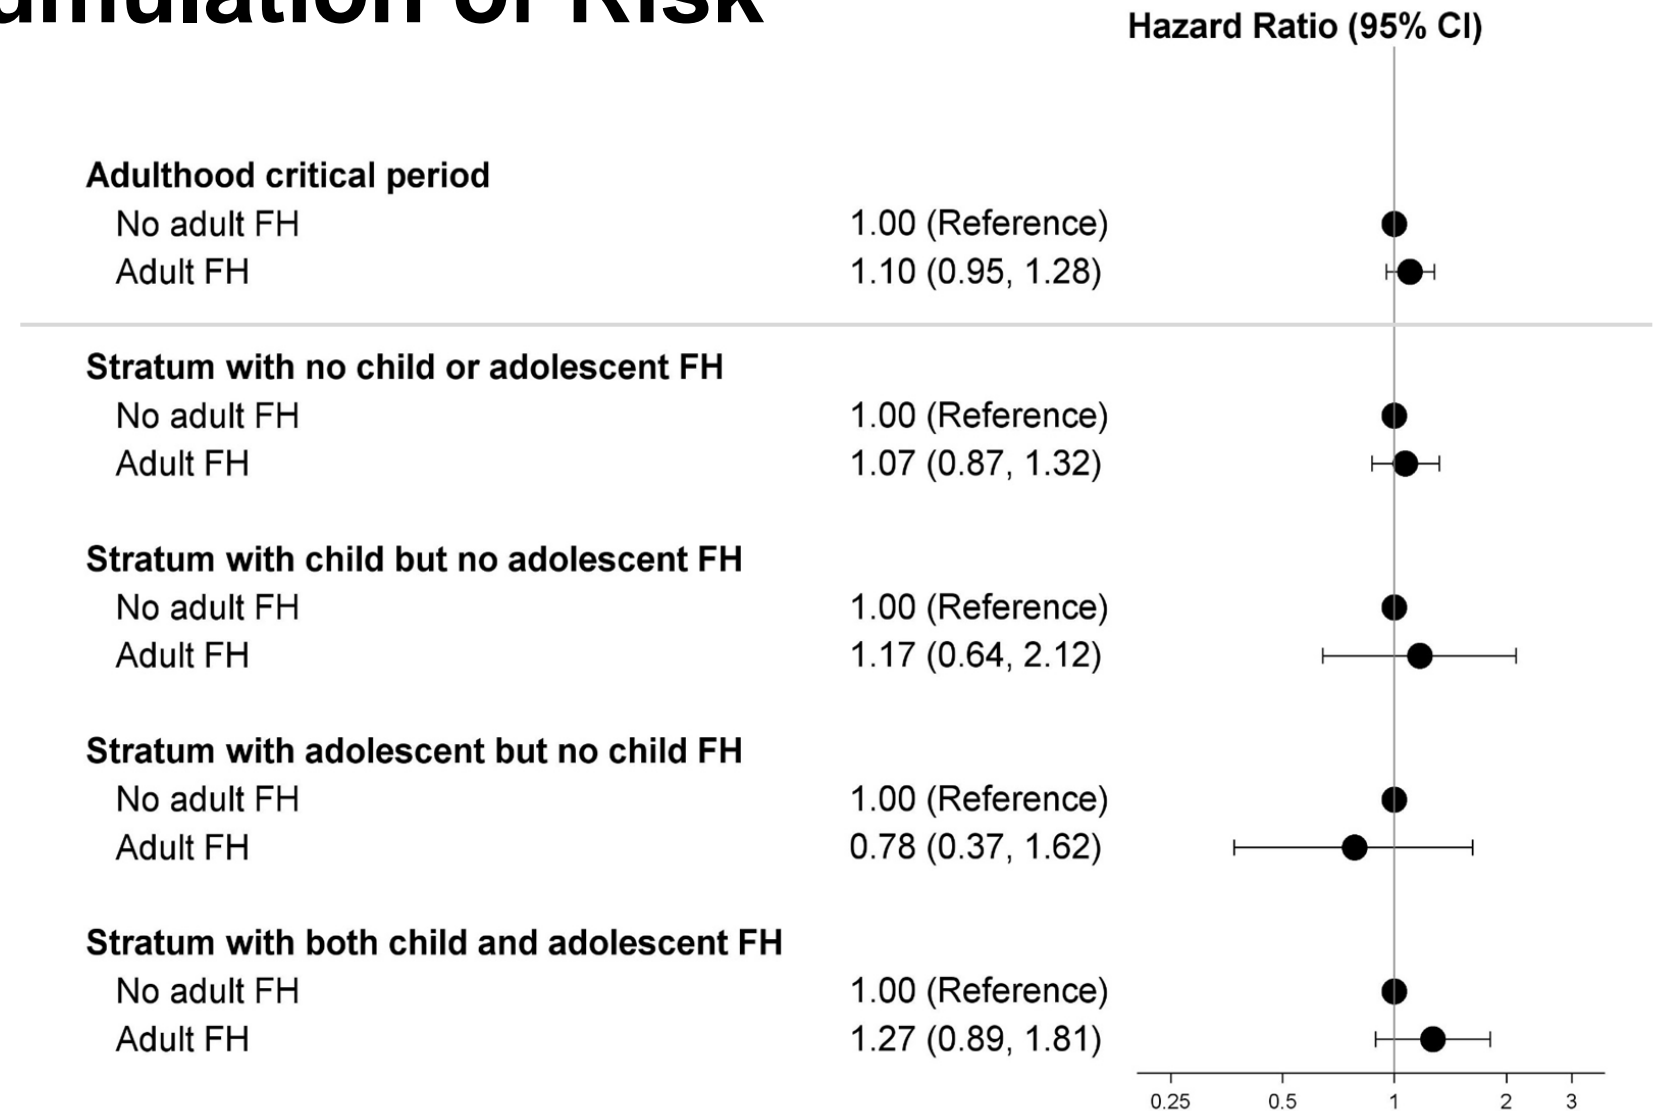

*FH = financial hardship*

# Results: Accumulation of Risk

*FH = financial hardship*

# Results: Accumulation of Risk

*FH = financial hardship*

# Limitations

- Measures do not capture precise timing, length, and severity of financial hardship
- Potential for residual and unmeasured confounding
- IPSW\*IPTW model misspecification
- Small number of participants identified as BIPOC (22% of the PRESTO cohort)
- PRESTO is an internet-based convenience sample of pregnancy planners with higher-than-average socioeconomic status, which limit generalizability of results

# Summary

- We observed a modest elevated risk of miscarriage among participants who experienced financial hardship, with the strongest effects for hardship in childhood
